Position Transducer

• **Potentiometer**
  • Linear and angular displacement
  • Inexpensive, easy to use

• **Linear variable differential Transformer (LVDT)**
  • Linear and angular position
  • Capable to measurement small displacement

• **Encoder**
  • Angular position
  • Rug and easily to interface with computer (digital output in nature)

• etc.
Potentiometer

Potentiometers – a resistive device with a linear or rotary sliding contacts.

Linear displacement: \[ R(x) = \frac{R_p}{L} x \] Where \( L \) is the total length, \( \Theta \) the total angular displacement, and \( R_p \) is the total resistance.

Angular displacement: \[ R(\theta) = \frac{R_p}{\Theta} \theta \]

Resolution = \[ \frac{\text{full scale displacement}}{\text{number of turns}} \]

Basic type of potentiometric displacement transducer.

Contact position

Resolution
Ex. It is necessary to measure the position of a panel. It moves 0.8 m. Its position must be known within 0.1 cm. Part of the mechanism which moves the panel is a shaft that rotates 250° when the panel is moved from one extreme to the other. A control potential has been found which is rated at 300° full scale movement. It has been 1000 turns of wire. Can this be used?

Solution  The shaft provides a conversion

\[
\frac{250°}{0.8 \text{ m}} = 312.5° / \text{m} \text{ or } 3.125° / \text{cm}
\]

A resolution of 0.1 cm at the panel translates into

\[0.1 \text{ cm} \times 3.125° / \text{cm} = 0.3125°\]

Required resolution for the potentiometer. The given potentiometer actually has a resolution of

\[
\frac{300°}{1000 \text{ turns}} = 0.300°
\]

The potentiometer can detect a change of 0.3°, which is finer than the required 0.3125°. So the available potentiometer will work.
Potentiometer

**Important Characteristics:**
- resolution
- linearity
- accuracy
- output span
- power rating and derating factor
- noise (electrical contact)
- starting and remain torque
- moment of inertia

**Self-heating**

Self-heating occurs because of the power dissipation in sensor, \( P_D = I^2 R_T \).

The increase in temperature from self-heating \( \Delta T \) due to \( P_D = I^2 R_T \) is

\[
P_D = \delta \Delta T \quad \text{or} \quad \Delta T = P_D \theta
\]

Where \( \delta \) is heat dissipation factor (mW/K)

\( \theta \) is thermal resistance (K/mW)

To minimize self-heating effect, the power dissipation must be limited.
**Ex.** A control potentiometer is rated as
- $150 \, \Omega$
- $1 \, \text{W (derate at 10 mW/°C above 65°C)}$
- $30^\circ\text{C/W thermal resistance}$

Can it be used with $10 \, \text{V supply at 80°C ambient temperature}?$

**Solution** The power dissipated by the potentiometer is

$$P = \frac{V^2}{R} = \frac{(10 \, \text{V})^2}{150 \, \Omega} = 667 \, \text{mW}$$

The actual temperature of the potentiometer

$$T_{pot} = T_{ambient} + P \theta$$
$$= 80^\circ\text{C} + (667 \, \text{mW})(30^\circ\text{C/W}) = 100^\circ\text{C}$$

The allowable power dissipation must be derated (decreased) by 10 mW for each degree above 65°C

$$P_{allowed} = P_{rated} - (T_{pot} - 65^\circ\text{C})(10 \, \text{mW/°C})$$
$$= 1000 \, \text{mW} - (100^\circ\text{C} - 65^\circ\text{C})(10 \, \text{mW/°C})$$
$$= 650 \, \text{mW}$$

Thus, the potentiometer can be used with the situation stated.
Potentiometer: Linearity

\[
V_{\text{ideal}} = \frac{R_1}{R_1 + R_2} V_{\text{in}} = \frac{R_1}{R_p} V_{\text{in}}
\]

\[
V_{\text{actual}} = \frac{R_1 \parallel R_L}{R_1 \parallel R_L + R_2} V_{\text{in}} = \frac{R_1 R_L}{R_1 R_L + R_1 R_2 + R_2 R_L} V_{\text{in}}
\]

Linearity: terminal base line

\[
\%\text{Linearity} = \frac{V_{\text{actual}} - V_{\text{ideal}}}{V_{\text{full scale}}} \times 100\%
\]

Here, full scale output = \( V_{\text{in}} \)

\[
\%\text{Linearity} = \left( \frac{R_1 R_L}{R_1 R_L + R_1 R_2 + R_2 R_L} - \frac{R_1}{R_p} \right) \times 100\%
\]
Potentiometer

**Ex.** Plot the transfer curve and determine endpoint linearity of a 1 kΩ potential driving a 5 kΩ load, powered from a 10 V source.

**Solution** here, we have

\[
V_{\text{desired}} = \frac{R_1}{R_p} V_{\text{in}} = \frac{R_1}{1000 \ \Omega} \times 10 \ V \quad V_{\text{full scale}} = V_{\text{in}} = 10 \ V
\]

\[
V_{\text{actual}} = \frac{R_1 \times 5000 \ \Omega}{R_1 \times 5000 \ \Omega + R_1 \times (1000 \ \Omega - R_1) + (1000 \ \Omega - R_1) \times 5000 \ \Omega} \times 10 \ V
\]

Linear Variable Differential Transformer (LVDT)

LVDT – an electromechanical device that produce an electrical output proportional to the displacement of a separate movable core

Circuit diagram for an LVDT. The secondary windings are normally connected in series opposition.

\[ e_o = e_{o1} - e_{o2} \]

Output voltages for a series-opposition connected LVDT.
Linear Variable Differential Transformer (LVDT)

The output voltage is linear function of core position as long as the motion of the core is within the operating of the LVDT. The direction of motion can be determined from the phase of the output voltage relative to the input voltage (primary coil).

Advantage
- Frictionless (no physical contact between the movable core and coil structure)
- Theoretical infinite resolution, resolution limited by the external electronics
- Isolation of exciting input and output (transformer action)
Linear Variable Differential Transformer (LVDT)

Block diagram of the readout circuit for an LVDT

\[ V_{out} = V_1(DC) - V_2(DC) \]

Phase sensitive demodulator based on (a) a half-wave rectifier and (b) full-wave rectifier
Linear Variable Differential Transformer (LVDT)

Assume the displacement varies with in the limited band.

Phase sensitive demodulator based on carrier multiplication

\[ x = x(t) \]
\[ S_A = x(t)K \sin 2\pi f_c t \]
\[ S_B = a \sin 2\pi f_c t \]
\[ S_{AxB} = aKx(t)(\sin 2\pi f_c t)^2 \]
\[ = aKx(t)(1 - \cos 4\pi f_c t) \]
\[ \frac{2}{2} \]

Strain ($\varepsilon$) is defined as a fractional change in length of a body due to an applied force.

Strain can be positive: tensile or negative strain: compressive. The practical unit is microstrain ($\mu\varepsilon$), which is $\varepsilon \times 10^{-6}$.

When a bar is strained with a uniaxial force, a phenomenon known as Poisson strain causes the bar diameter, $D$ to contract in transverse direction. The magnitude of this contraction is a material property indicated by its Poisson’s Ratio, $\nu$

$$\nu = \frac{-\varepsilon_t}{\varepsilon} = \frac{-\Delta D / D}{\Delta L / L}$$

For most metal: $\nu \sim 0.3$, polymer: $\nu > 0.3$
**σ - ε Curve, Brittle and Ductile materials**

Typical σ - ε curve from a tensile test on a ductile polycrystalline metal (e.g. aluminum alloys, brasses, bronzes, nickel etc.)

- **σ_y** – Yield strength
  The maximum stress before the plastic deformation occurs.

- **σ_TS** – Tensile strength
  The maximum stress at σ - ε curve

- **σ_f** – Fracture strength
  The stress at instance of fracture
Strain Gages: Derivation of Gage Factor

Strain gage is a device whose electrical resistance varies in proportion to the amount of strain the device. (discovery by Lord Kelvin in 1856)

The electric resistance of a wire having length $l$, cross section $A$, and resistivity $\rho$ is

$$ R = \rho \frac{l}{A} $$

The change of $R$ can be affected by three quantities, and is given by

$$ \frac{dR}{R} = \frac{d\rho}{\rho} + \frac{dL}{L} - \frac{dA}{A} $$

Consider a wire under an applied force $F$ within the elastic limit, for a wire with a diameter $D$

$$ A = \frac{\pi D^2}{4} \quad \Rightarrow \quad \frac{dA}{A} = 2 \frac{dD}{D} = -2\nu \frac{dL}{L} $$

Therefore the geometry change results in the $R$ change as follows

$$ \frac{dR}{R} = (1+2\nu) \frac{dL}{L} + \frac{d\rho}{\rho} $$
Derivation of Gage factor: continue

Sensitivity of a strain gage: Gage factor (K) is defined as

\[ K = \frac{dR}{dL} = \frac{dR}{L} \frac{\rho}{\rho} = 1 + 2\nu + \frac{d\rho}{\rho} \]

Note: The change in resistivity as a result of a mechanical strain is called \textit{piezoresistive effect}.

Therefore, the resistance of the strain gage under an applied force is

\[ R = R_0 + dR = R_0 \left(1 + \frac{dR}{R_0}\right) = R_0 \left(1 + K \varepsilon\right) \]

where \( R_0 \) is the resistance where there is no applied stress.
Ex A strain gage is bonded to a steel beam which is 10.00 cm long and has a cross-sectional area of 4.00 cm². Young’s modulus of elasticity for steel is 20.7x10¹⁰ N/m². The strain gage has a nominal (unstrained) resistance of 240 Ω and a gage factor 2.20. When a load is applied, the gage’s resistance changes by 0.013 Ω. Calculate the change in length of steel beam and the amount of force applied to the beam.

**SOLUTION**

\[
K = \frac{\Delta R / R}{\Delta L / L}
\]

\[
\Delta L = \frac{L}{K} \left( \frac{\Delta R}{R} \right) = \frac{0.1 \text{ m}}{2.20} \times \frac{0.013 \Omega}{240 \Omega} = 2.46 \times 10^{-6} \text{ m}
\]

From \( \sigma = E \varepsilon \) where \( \varepsilon = \frac{\Delta L}{L} \) and \( \sigma = \frac{F}{A} \)

Therefore \[ \frac{F}{A} = E \frac{\Delta L}{L} \] or \[ F = E \frac{\Delta L}{L} A \]

\[ A = 4 \text{ cm}^2 \times \frac{1 \text{ m}^2}{10^4 \text{ cm}^2} = 4 \times 10^{-4} \text{ m}^2 \]

\[ F = 20.7 \times 10^{10} \frac{\text{N}}{\text{m}^2} \times \frac{2.46 \times 10^{-6} \text{ m}}{0.1 \text{ m}} \times 4 \times 10^{-4} \text{ m} \]

\[ = 2.037 \times 10^3 \text{ N} \]
Strain Gage

Ideally, we would prefer the strain gage to change resistance only in respect to the stress-induced strain in the test specimen, but the resistivity and the strain sensitivity of all known strain sensitive materials vary with temperature.

The resistance of a conductor at a given temperature, $T$ is

$$R_T = R_{T_0} (1 + \alpha_0 \Delta T)$$

Where $R_{T_0}$ is the resistance at the reference temperature $T_0$, $\alpha_0$ is the temperature coefficient and $\Delta T$ is the change in temperature from $T_0$.

**Ex** Calculate the change in resistance caused by a $1^\circ\text{C}$ change in temperature for the strain gage in the previous example. The temperature coefficient $\alpha_0$ for most metals is $0.003925/\circ\text{C}$.

**SOLUTION**

$$\Delta R = (0.003925/\circ\text{C})(1^\circ\text{C})(240 \Omega) = 0.942 \Omega$$

But the stress applied by the load in the previous example caused only a $0.0013 \Omega$ change in the strain gage’s resistance.

$$\frac{\Delta R_{\text{Temp}}}{\Delta R_{\text{stress}}} = \frac{0.942 \Omega}{0.013 \Omega} = 72.5$$

Therefore, it is necessary to compensate for temperature effect on the strain gage.
Wheatstone Bridge: Deflection Method

Wheatstone bridges are often used in the deflection mode: This method measures the voltage difference between both dividers or the current through a detector bridging them.

With no stress $\Delta R = 0$, all four resistors are equal, so $V_{out} = 0$. When stress is applied, the strain gage changes its resistance by $\Delta R$.

\[
V_{out} = \frac{R}{R+R} E - \frac{R}{R+(R+\Delta R)} E
\]

\[
= \frac{\Delta R}{4R+2\Delta R} E
\]

While $\Delta R$ is typically 0.01 $\Omega$, so in practice $R >> \Delta R$

\[
V_{out} \approx \frac{\Delta R}{4R} E
\]

\[
V_{out} \approx \frac{KE}{4} \varepsilon
\]
Temperature Compensation

Placement of active and dummy gages for temperature compensation

Ex Determine $V_{out}$ given that $R_0 = 240 \, \Omega$, $E = 10 \, V$ and 
(a) Stress cause the upper resistor (the active gage) on the right to increase by 0.013 $\Omega$.
(b) Temperature causes both resistors (active and dummy) on the right to increase by 9.4 $\Omega$.
(c) Stress cause the active gage to increase by 0.013 $\Omega$ and temperature both resistors to increase by 9.4 $\Omega$.

SOLUTION (a) \[ V_{out} = \frac{\Delta R}{4R} E = \frac{(0.013\Omega)(10 \, V)}{4(240\Omega)} = 0.13 \, \text{mV} \]

The stress produces a rather small signal.
Temperature Compensation

(b) Using the voltage-divider give us

\[ V_{out} = \frac{(240 \, \Omega)(10 \, V)}{(240 \, \Omega + 240 \, \Omega)} - \frac{(249.4 \, \Omega)(10 \, V)}{(249.4 \, \Omega + 249.4 \, \Omega)} \]

\[ = 5 \, V - 5 \, V = 0 \, V \]

The use of a dummy gage eliminates the effect of temperature.

(c) With both a temperature and a stress-induced resistance change,

\[ V_{out} = \frac{(240 \, \Omega)(10 \, V)}{(240 \, \Omega + 240 \, \Omega)} - \frac{(249.4 \, \Omega)(10 \, V)}{(249.4 \, \Omega + (249.4 \, \Omega + 0.013 \, \Omega))} \]

\[ = 5 \, V - 4.99987 \, V = 0.13 \, mV \]

So even in the presence of both stress and temperature resistance changes, the use of a dummy gage eliminates the effect of the temperature change.
Strain gage arrangements

**Single active strain gage**

\[ V_{out} \approx \frac{\Delta R}{4R} E \]

**Four active strain gage (Full bridge)**

\[ V_{out} \approx \frac{\Delta R}{R} E \]

**Two active strain gage (Half bridge)**

\[ V_{out} \approx \frac{\Delta R}{2R} E \]
Effect of Lead Wire Resistance

![Circuit Diagrams](image-url)
Effect of Lead Wire Resistance: Defection method

In strain gage application, we can write

\[ V_o \approx \frac{V_r \Delta R}{4R} \]

But, with lead wire, \( R_3 = R_0 + 2R_W \)

Therefore, with three-wire connection the reduction in sensitivity is smaller.

Two-wire connections of Quarter-Bridge Circuit

Siemens or Three-wire connections of Quarter-Bridge Circuit
Effect of Lead Wire Resistance: Defection method

Temperature effect

Two-wire connections of Quarter-Bridge Circuit

Siemens or Three-wire connections of Quarter-Bridge Circuit

The detrimental effect resulting from lead wires is loss of temperature compensation

The detrimental effect of long lead wires can be reduced by employing the three-wire system
Load Cell

The performance of strain gage depends heavily on the installation, the proper alignment with an applied force, gage adhesion with the specimen etc.

Load cell – a force transducer consists of a beam with properly mounted strain gages (usually four)

Load cell specifications

<table>

</tr>
</tbody>
</table>

The Model 5341, 5353 and 5354 load cells are very accurate strain gage sensors used for weighing and force measurement. Their high accuracy makes them ideally suited for critical weighing applications. The 5353 and 5354 Models are sealed devices that offer the durability and ruggedness required of units used in production environments. The Model 5341 is a lower range unit intended for controlled environments.
Load Cell

**Ex** A GSE5352 load cell has a full-scale rating of 500 lb.
(a) What is the recommended excitation voltage?
(b) Using that excitation, what is the output voltage per pound?
(c) What is the nonlinearity in pounds?
(d) What is the zero shift (in pounds) if the temperature varies across its rated range?

**SOLUTION**
(a) The manufacturer recommends a 10-V dc excitation

\[ V_{\text{out(max)}} = (\text{output at rated capacity})(V_{\text{excitation}}) = (2 \text{ mV/V})(10 \text{ V}) = 20 \text{ mV} \]

(b) \[ V_{\text{out/lb}} = V_{\text{out/lb}} / \text{full-scale load} = 20 \text{ mV/500 lb} = 40 \mu \text{V/lb} \]

This means that your electronics must be able to clearly and accurately amplify differential signals of 40 \(\mu\text{V}\) or less if you expect to resolve and display 1-lb increments.

(c) \[ \text{Nonlinearity} = (\pm 0.05\%)(500 \text{ lb}) = \pm 0.25 \text{ lb} \]

So no matter how good your electronics, there will be a \(\pm 0.25\)-lb uncertainty.

(d) The temperature range is +25 to +125\(^\circ\)F. This represents a 100\(^\circ\)F shift. This zero shift with temperature is +0.002\% FS/\(^\circ\)F

\[ \text{Zero shift} = (+0.02\% / \^\circ \text{F})(100^\circ \text{F})(500 \text{ lb}) = +1 \text{ lb} \]

So if the transducer experience significant changes in temperature, you must readjust zero.
